

Account-Level Linking, Evidence

NovaTech Revenue Intelligence Dashboard | One account traced across all three views

Purpose. The brief asked for account-level linking, so that the same customer can be followed from the campaign that generated the lead, through the deal, to the support tickets that came after. This document demonstrates that working. A single account is selected once, and all three views respond. Every figure shown reconciles against the others and against the unfiltered totals.

The account under test

Falcon Software (ACCT-011) was chosen because it sits at the top of the at-risk list: \$20,912 in won revenue with 41% of its support tickets filed in a negative tone. It is the account the dashboard is designed to surface, so it is the right one to trace end to end.

Selecting it in the Account control on Customer Health sets a parameter that every sheet reads. No further action is needed on the other two views, the selection travels with the user.

View 1, Customer Health

Customer Health filtered to ACCT-011. All five KPI cards, the at-risk table and the sentiment breakdown respond to a single selection. The at-risk table correctly reduces to one row.

Reconciliation. The sentiment donut reads 16 neutral, 15 negative, 5 positive and 1 not recorded, which sums to 37 and matches the Total tickets card exactly. Negative sentiment of 15 out of 37 is 40.54%, matching the KPI card to two decimal places and rounding to the 41% shown in the at-risk table. The filter is reaching every visual on the sheet, not just the table it was applied from.

View 2, Sales Pipeline

Sales Pipeline, same account. Twelve deals, nine won, \$20,912 in won revenue. Win rate by region collapses to Central alone, and the product chart narrows to the four products this account actually bought.

Reconciliation. Nine won deals out of twelve is 75.0%, matching the Win rate card. Nine won deals at an average of \$2,324 gives \$20,916, which is the \$20,912 card figure with rounding in the average. Most importantly, that \$20,912 is the same figure carried in the revenue column of the at-risk table on Customer Health, a table built on the joined dataset. The two views agree because they are reading the same account through the same key.

View 3, Marketing Funnel

exists. Marketing simply is not crediting it.

This matters well beyond one account. The dashboard reports an average campaign return of -90.3% across all six campaigns, \$12.36M spent against \$1.13M attributed. Falcon Software is a worked example of how a number like that is produced without any campaign actually failing: revenue is earned, and the link back to the campaign that generated the lead is never made. It is the difference between a marketing problem and a measurement problem, and it is the reason the recommendation in the executive summary is to audit attribution before cutting any budget.

It also confirms the at-risk logic is working as intended. Falcon Software holds above-median revenue, files tickets at nearly double the company negative-sentiment rate, waits 22.5% longer than average for resolution, and takes 18% longer to close its deals. Every component of the risk definition is visible in the filtered views, which is what makes the at-risk table defensible rather than an arbitrary shortlist.

Interaction mechanics

Mechanism	Where it lives	What it does
Account parameter	Analysis level, read by all three sheets	Holds the selected account. A control sets its value; a filter on each sheet reads that value and applies it, with cross-dataset scope enabled so it reaches visuals built on any of the four datasets.
Segment filter	Marketing Funnel and Customer Health	Cross-sheet filter on customer segment. Required adding an identically named calculated column to each dataset, because cross-dataset filtering matches fields by name only.
Filter action	At-risk accounts table	One click on a row filters the ticket volume and sentiment visuals beside it.
Navigation action	At-risk accounts table, menu trigger	Carries the selected account to Sales Pipeline and sets the parameter on arrival, so the destination sheet opens already filtered to that account.

All figures reconciled against each other and against the unfiltered dashboard totals: 2,240 leads, 499 deals, 3,000 tickets.
